Lecture 17: High-dimensional regression, non-linear regression

Reading: Sections 6.4, 7.1

STATS 202: Data mining and analysis

Sergio Bacallado
November 1, 2013

Announcements

- The midterm's solutions are online.
- I will bring the graded midterms on Monday.
- The evaluation metric in the Kaggle competition was changed from the Mean Absolute Error, to the Mean Squared Error.

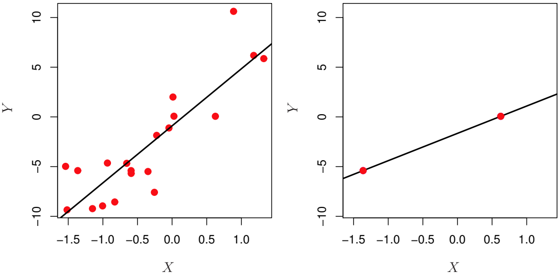
High-dimensional regression

- Most of the methods we've discussed work best when n is much larger than p.
- However, the case $p \gg n$ is now common, due to experimental advances and cheaper computers:

  1. **Medicine:** Instead of regressing heart disease onto just a few clinical observations (blood pressure, salt consumption, age), we use in addition 500,000 single nucleotide polymorphisms.
  2. **Marketing:** Using search terms to understand online shopping patterns. A *bag of words* model defines one feature for every possible search term, which counts the number of times the term appears in a person's search. There can be as many features as words in the dictionary.

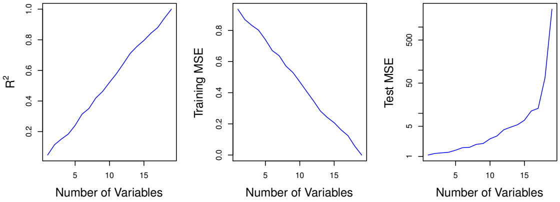
Some problems we have talked about

- We know that least-squares regression doesn't work when $p > n$.
- We can use regularization methods, such as variable selection, ridge regression and the lasso.
- When $n = p$, we can find a fit that goes through every point.

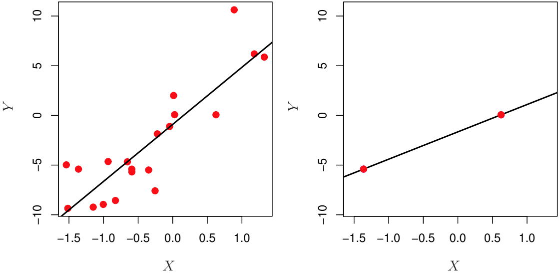


Some problems we have talked about

- We know that least-squares regression doesn't work when $p > n$.
- We can use regularization methods, such as variable selection, ridge regression and the lasso.
- When $n = p$, we can find a fit that goes through every point.
- Measures of training error are really bad.

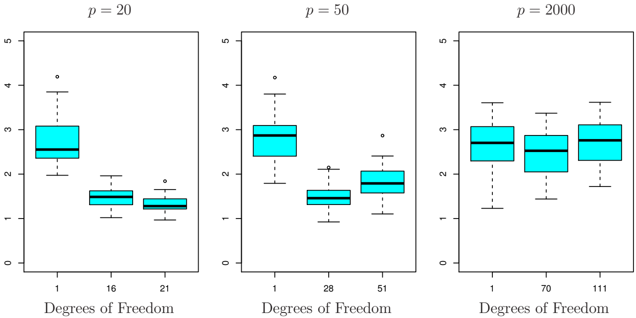


Some new problems



- Furthermore, it becomes hard to estimate the noise $\hat{\sigma}^2$.
- Measures of model fit C_p, AIC, and BIC fail.

Some new problems



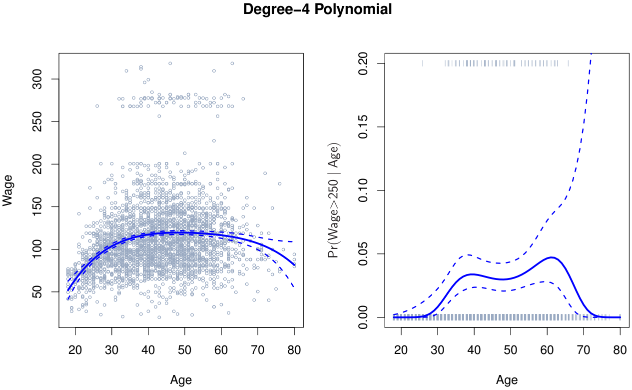
- In each case, only 20 predictors are associated to the response.
- Plots show the test error of the Lasso.
- **Message:** Adding predictors that are uncorrelated with the response hurts the performance of the regression!

Interpreting coefficients when $p > n$

- When $p > n$, every predictor is a linear combination of other predictors, i.e. there is an extreme level of multicollinearity.
- The Lasso and Ridge regression will choose one set of coefficients.
- The coefficients selected $\{i\ ;\ |\hat{\beta}_i| > \delta\}$ are not guaranteed to be identical to $\{i\ ;\ |\beta_i| > \delta\}$. There can be many sets of predictors (possibly non-overlapping) which yield good models.
- **Message:** Don't overstate the importance of the predictors selected.

Non-linear regression

Problem: How do we model a non-linear relationship?



Left: Regression of `wage` onto `age`.
Right: Logistic regression for classes `wage`> 250 and `wage`≤ 250

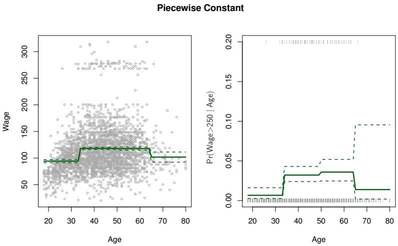
Basis functions

Strategy:

- Define a model:

$$Y = \beta_0 + \beta_1 f_1(X) + \beta_2 f_2(X) + \cdots + \beta_d f_d(X).$$

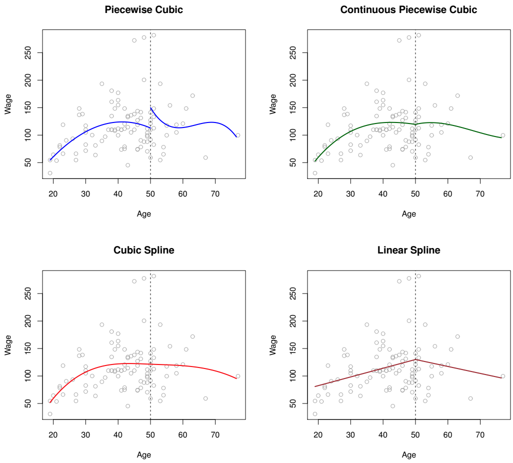
- Fit this model through least-squares regression.
- Options for $f_1, \ldots, f_d$:
  1. Polynomials, $f_i(x) = x^i$.
  2. Indicator functions, $f_i(x) = \mathbf{1}(c_i \leq x < c_{i+1})$.



Basis functions

- Options for $f_1, \ldots, f_d$:

  3. Piecewise polynomials:



Cubic splines

- Define a set of knots $\xi_1 < \xi_2 < \cdots < \xi_K$.
- We want the function $Y = f(X)$ to:

  1. Be a cubic polynomial between every pair of knots ξ_i, ξ_{i+1}.
  2. Be continuous at each knot.
  3. Have continuous first and second derivatives at each knot.

- It turns out, we can write f in terms of $K + 3$ basis functions:

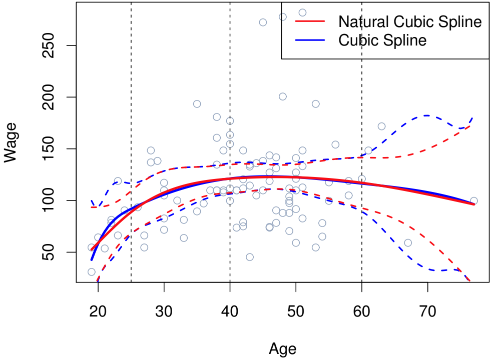
$$f(X) = \beta_0 + \beta_1 X + \beta_2 X^2 + \beta_3 X^3 + \beta_4 h(X, \xi_1) + \cdots + \beta_{K+3} h(X, \xi_K)$$

where,

$$h(x, \xi) = \begin{cases} (x - \xi)^3 & \text{if } x > \xi \\ 0 & \text{otherwise} \end{cases}$$

Natural cubic splines

Spline which is linear instead of cubic for $X < \xi_1$, $X > \xi_K$.

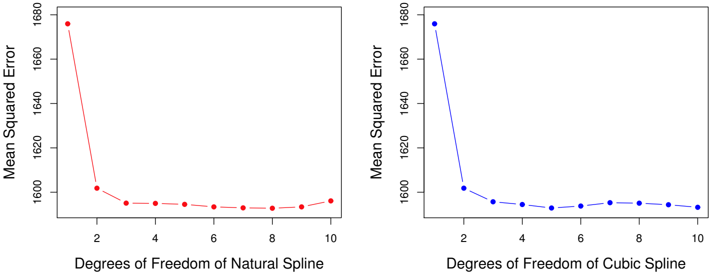


The predictions are more stable for extreme values of X.

Choosing the number and locations of knots

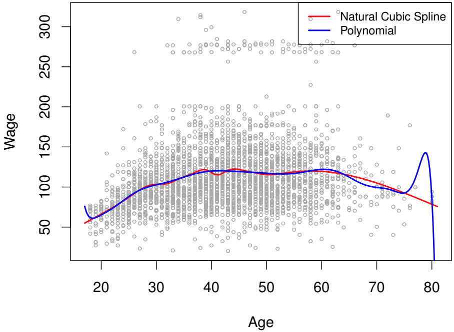
The locations of the knots are typically quantiles of X.

The number of knots, K, is chosen by cross validation:



Natural cubic splines vs. polynomial regression

- Splines can fit complex functions with few parameters.
- Polynomials require high degree terms to be flexible.
- High-degree polynomials can be unstable at the edges.



Smoothing splines

Find the function f which minimizes

$$\sum_{i=1}^{n}(y_i - f(x_i))^2 + \lambda \int f''(x)^2 dx$$

- The RSS of the model.
- A penalty for the roughness of the function.

Facts:

- The minimizer $\hat{f}$ is a natural cubic spline, with knots at each sample point $x_1, \ldots, x_n$.
- Obtaining $\hat{f}$ is similar to a Ridge regression.

Deriving a smoothing spline

1. Show that if you fix the values $f(x_1), \ldots, f(x_2)$, the roughness

$$\int f''(x)^2 dx$$

   is minimized by a natural cubic spline.

2. Deduce that the solution to the smoothing spline problem is a natural cubic spline, which can be written in terms of its basis functions.

$$f(x) = \beta_0 + \beta_1 f_1(x) + \ldots \beta_{n+3} f_{n+3}(x)$$

3. Letting $\mathbf{N}$ be a matrix with $\mathbf{N}(i,j) = f_j(x_i)$, we can write the objective function:

$$(y - \mathbf{N}\beta)^T (y - \mathbf{N}\beta) + \lambda \beta^T \Omega_{\mathbf{N}} \beta,$$

   where $\Omega_{\mathbf{N}}(i,j) = \int N_i''(t) N_j''(t) dt$.

Deriving a smoothing spline

4. By simple calculus, the coefficients $\hat{\beta}$ which minimize

$$(y - \mathbf{N}\beta)^T (y - \mathbf{N}\beta) + \lambda \beta^T \Omega_{\mathbf{N}} \beta,$$

   are $\hat{\beta} = (\mathbf{N}^T\mathbf{N} + \lambda\Omega_{\mathbf{N}})^{-1}\mathbf{N}^T y$.

5. Note that the predicted values are a linear function of the observed values:

$$\hat{y} = \underbrace{\mathbf{N}(\mathbf{N}^T\mathbf{N} + \lambda\Omega_{\mathbf{N}})^{-1}\mathbf{N}^T}_{\mathbf{S}_\lambda} y$$
